

### **Databases for Analytics**

Kroenke / Auer Chapter 1
Introduction to Database Concepts

#### **Learning Objectives**

- Skills: You should know how to ...
  - Identify the parts of a database table
  - Use keys to match records from separate tables
- Theory: You should be able to explain ...
  - Importance of databases for web and mobile apps
  - Features and components of database systems
  - Difference between mobile, desktop, and enterprise platforms
  - Functions of a DB Management System
  - Terminology like apps, layers, DBMS, SQL, metadata, etc.

# **Big Picture Stuff**

Before we talk about relational databases

#### Why Study Databases?

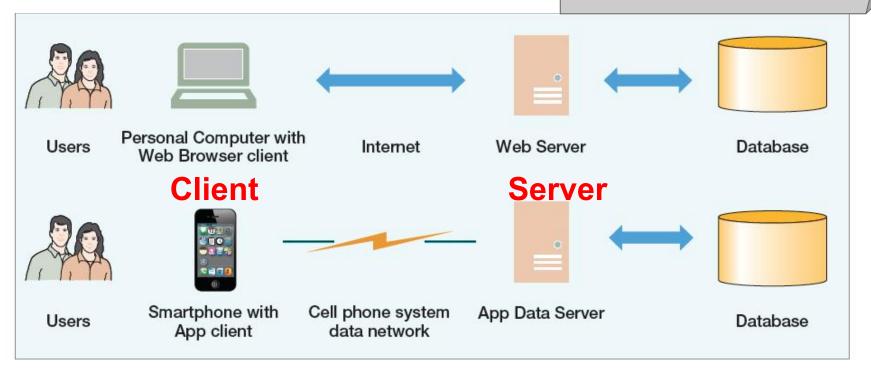

Access to data and information are fundamental to modern business

- Management is about decision making
- Good decisions require information
- Good information requires relevant, accurate, and timely data

Important to understand how databases work and interact with business applications

#### **Enterprise Architecture**

Access to data is indirect, through a server process rather than data files. Every mobile or web app has this client-server architecture.

#### **Data and Information**

- Data = raw facts
- Information = Data + Metadata
- Metadata includes things like
  - Meaning of the data
  - Source, timing, and format of data
- Difference is mostly a matter of perspective
  - Information is the product of data processing
  - Databases are designed to provide information

#### Implications for Analysts

- Data Analysis = deriving information from data to support a task or decision
  - Database System → Required Information
- Database Design = making decisions about how to generate, store, and retrieve data to best support data usage
  - Information Required → Database System

but we also need to know about this as well

focused here ...

#### What's a Database? DBMS?

- A database is an integrated, shared repository of data + metadata
- A database management system (DBMS)
  - controls access (generation, storage, retrieval) to data and metadata
  - provides facilities to structure the data (with metadata)
- RDBMS vs NoSQL

#### **Relational Databases**

Before you go NoSQL like the cool kids, you should know about RDBMSs

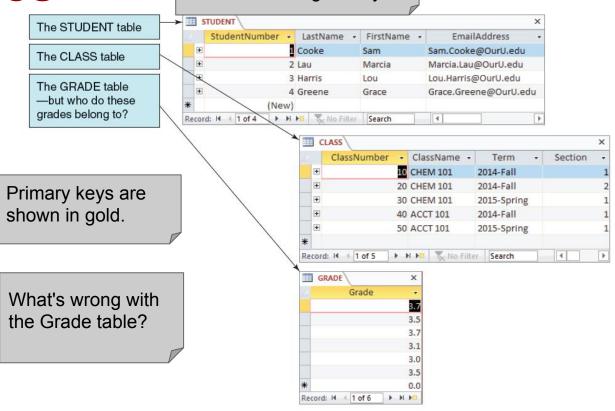

#### What is a Relational Database?

- Data is stored in tables, which have rows and columns like a spreadsheet. A database may have multiple tables, where each table stores data about a different kind of entity ('thing').
- Each row in a table stores data about an occurrence or instance of the thing of interest. Each column ('field') represents an attribute of the thing.
- A database stores data (about the things) and metadata (data types, relationships, etc.).

#### **Data in Tables**

A primary key (PK) is a unique identifier within a table.

A surrogate key is a PK that is automatically assigned by the DBMS.

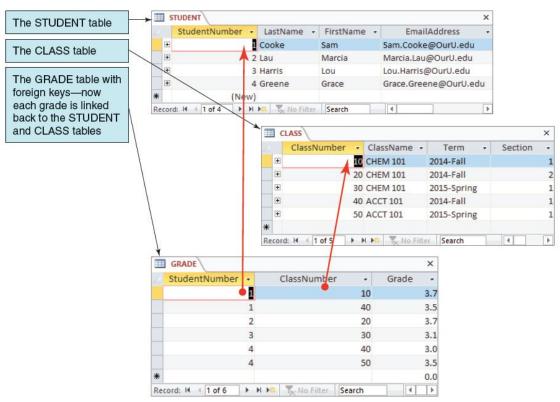

StudentNumber is both a

PK and a surrogate key.

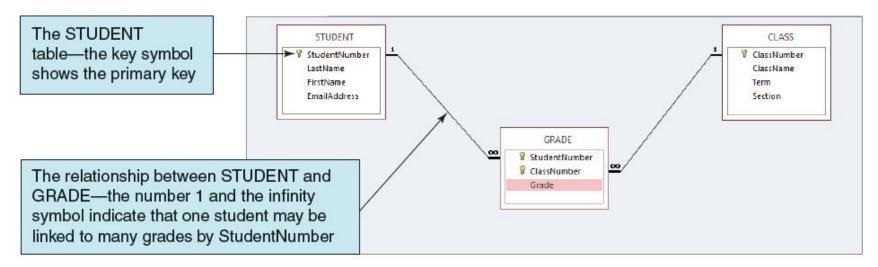

#### **Table Relationships**

A foreign key (FK) is a link (red arrow) from one record to another record. The FK matches up with the PK of the other record (usually in a different table).

#### **Another Perspective ...**

The Relationship graph below can be drawn **before** we have data.

#### **Notes on Notation ...**

- Table names are written with all capital letters:
  - STUDENT, CLASS, GRADE, COURSE\_INFO
- Column names are written in "CamelCase," with no spaces and a capital letter on each word (including the first):
  - o Term, Section, ClassNumber, StudentName

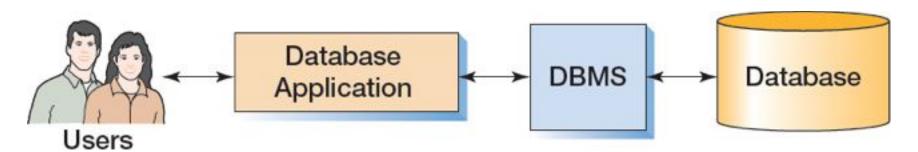

#### **Database Application Examples**

| Application                                  | Example<br>Users   | Number<br>of Users   | Typical Size            | Remarks   |
|--|--|----------------------|-------------------------|---|
| Sales contact<br>manager                     | Salesperson  | 1                    | 2,000 rows              | Products such as GoldMine and Act! are database centric.  |
| Patient appointment (doctor, dentist)        | Medical office   | 15 to 50             | 100,000 rows            | Vertical market software vendors incorporate databases into their software products.                              |
| Customer<br>relationship<br>management (CRM) | Sales, marketing,<br>or customer<br>service<br>departments | 500                  | 10 million rows         | Major vendors such as Microsoft<br>and Oracle PeopleSoft<br>Enterprise build applications<br>around the database. |
| Enterprise resource planning (ERP)           | An entire organization                                     | 5,000                | 10 million+<br>rows     | SAP uses a database as a central repository for ERP data.   |
| E-commerce site                              | Internet users   | Possibly<br>millions | 1 billion+<br>rows      | Drugstore.com has a database<br>that grows at the rate of<br>20 million rows per day!                             |
| Digital dashboard                            | Senior managers  | 500                  | 100,000 rows            | Extractions, summaries, and consolidations of operational databases.  |
| Data mining                                  | Business analysts  | 25                   | 100,000 to<br>millions+ | Data are extracted, reformatted, cleaned, and filtered for use by statistical data mining tools.                  |

# **Database Systems**

**Databases in Context** 

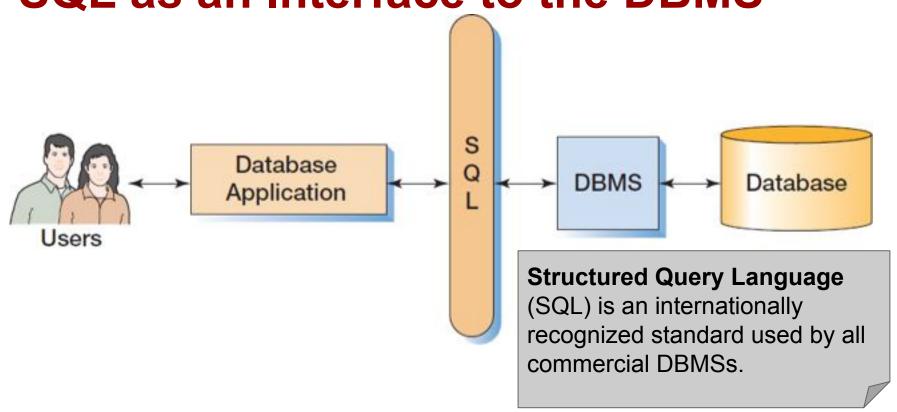

#### **DB System Components ("layers")**

**Applications** are the computer programs that users work with.

The **Database Management System** (DBMS) creates,
processes, and administers
databases.

#### SQL as an Interface to the DBMS

#### **Application layer vs DBMS layer**

# Basic Functions of Application Programs Create and process forms Process user queries Create and process reports Execute application logic Control the application itself Visible to the end user as

Visible to the end user as system use cases with results shown on the screen.

| Functions of a D  | вмѕ            |  |
|---|----------------|--|
| Create database   |                |  |
| Create tables   |                |  |
| Create supporting structures (e.g., indexes)              |                |  |
| Modify (insert, update, or delete) database data          |                |  |
| Read database data  |                |  |
| Maintain database structures end user but required to car |                |  |
| Enforce rules   | out the system |  |
| Control concurrency use cases.                            |                |  |
| Perform backup and recovery                               |                |  |

#### The Database (again)

- •A database is a self-describing collection of integrated tables.
- •The tables are called **integrated** because they store data about the relationships between the rows of data.
- •A database is called **self-describing** because it stores a description of itself.
- •The self-describing data is called **metadata**, which is data about data.

#### Metadata

Metadata is stored in tables, just like any other data, except it is about the tables and columns.

The **USER\_TABLES** table has metadata about tables.

The **USER\_COLUMNS** table has metadata about columns.

Note that **TableName** is used as a PK/FK pair to relate columns to tables.

#### Can you guess how this works?

#### **USER TABLES Table**

| TableName | NumberColumns | PrimaryKey                   |
|-----------|---------------|------------------------------|
| STUDENT   | 4             | StudentNumber                |
| CLASS     | 4             | ClassNumber                  |
| GRADE     | 3             | (StudentNumber, ClassNumber) |

#### **USER COLUMNS Table**

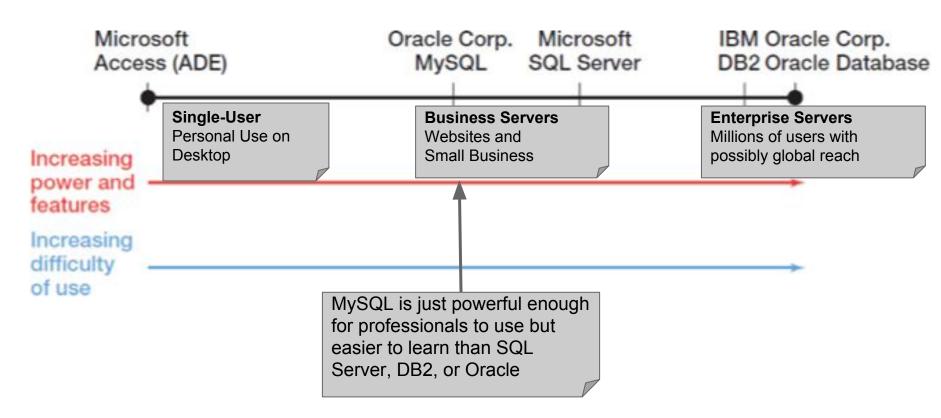

| ColumnName    | TableName | DataType | Length (bytes) |
|---------------|-----------|----------|----------------|
| StudentNumber | STUDENT   | Integer  | 4              |
| LastName      | STUDENT   | Text     | 25             |
| FirstName     | STUDENT   | Text     | 25             |
| EmailAddress  | STUDENT   | Text     | 100            |
| ClassNumber   | CLASS     | Integer  | 4              |
| Name          | CLASS     | Text     | 25             |
| Term          | CLASS     | Text     | 12             |
| Section       | CLASS     | Integer  | 4              |
| StudentNumber | GRADE     | Integer  | 4              |
| ClassNumber   | GRADE     | Integer  | 4              |
| Grade         | GRADE     | Decimal  | (2, 1)         |

#### **Commonly-used DBMS Products**

- Microsoft Access
- Microsoft SQL Server
- Oracle Corporation Oracle Database
- MySQL Server
- IBM DB2

We will be using **MySQL Server** in this class, but will try to avoid anything nonstandard that wouldn't also apply to the others.

#### Power vs Ease of Use

#### **Some Light History**

| Era                            | Years       | Important<br>Products                   | Remarks   |
|--------------------------------|-------------|---|---|
| Predatabase                    | Before 1970 | File managers                           | All data were stored in<br>separate files. Data<br>integration was very<br>difficult. File storage<br>space was expensive<br>and limited. |
| Early database                 | 1970–1980   | ADABAS, System2000,<br>Total, IDMS, IMS | First products to provide<br>related tables. CODASYL<br>DBTG and hierarchical<br>data models (DL/I) were<br>prevalent.                    |
| Emergence of relational model  | 1978–1985   | DB2, Oracle                             | Early relational DBMS products had substantial inertia to overcome. In time, the advantages weighed out.                                  |
| Microcomputer<br>DBMS products | 1982-1992+  | dBase-II, R:base,<br>Paradox, Access    | Amazing! A database on a micro. All micro DBMS products were eliminated by Microsoft Access in the early 1990s.                           |
| Object-oriented DBMS           | 1985–2000   | Oracle ODBMS and others                 | Never caught on. Required relational database to be converted. Too much work for perceived benefit.                                       |

| Era                                   | Years            | Important<br>Products   | Remarks   |
|---------------------------------------|------------------|---|---|
| Web databases                         | 1995-<br>present | IIS, Apache, PHP,<br>ASP.NET, and Java                                  | Stateless characteristic of<br>HTTP was a problem at<br>first. Early applications<br>were simple one-stage<br>transactions. Later, more<br>complex logic developed.   |
| Open source<br>DBMS products          | 1995-<br>present | MySQL, PostgresQL,<br>and other products                                | Open source DBMS products provide much of the functionality and features of commercial DBMS products at reduced cost.   |
| XML and Web<br>services               | 1998-<br>present | XML, SOAP, WSDL,<br>UDDI, and other<br>standards                        | XML provides tremendous<br>benefits to Web-based<br>database applications. Very<br>important today. May<br>replace relational databases<br>during your career. See<br>Chapter 11 and Appendix K.  |
| Big Data and the<br>NoSQL<br>movement | 2009-<br>present | Hadoop, Cassandra,<br>Hbase, CouchDB,<br>MongoDB, and other<br>products | Web applications such as Facebook and Twitter use Big Data technologies, often using Hadoop and related products. The NoSQL movement is really a NoRelationalDB movement that replaces relational databases with non-relational data structures. See Chapter 12 and Appendix K. |

# Implications of Database Design

Why Data Analysts should know about design

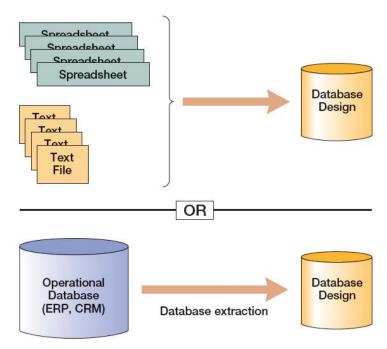

#### Importance of Design

Databases must fit the expected users, business operations, facilities, and needs of the organization.

- Good design provides
  - Shared data management (across whole org)
  - Access to accurate, timely, and relevant information
- Bad design leads to
  - Difficult-to-trace errors
  - Degraded ability to make and execute decisions

#### **Effect of Data Sources**

How a database is designed depends somewhat on the provenance, timeliness, integrity, and organization of the source data.

Copyright © 2016, by Pearson Education, Inc.,

#### Normalization: One Table vs Two Tables

One-table design has plenty of redundancy (and potential typos) but is darn convenient.

Two-table design has higher integrity (less redundancy) but requires logic to connect the tables.

| EmpNum | EmpName  | DeptNum | DeptName   |
|--------|----------|---------|------------|
| 100    | Jones    | 10      | Accounting |
| 150    | Lau      | 20      | Marketing  |
| 200    | McCauley | 10      | Accounting |
| 300    | Griffin  | 40      | Accounting |

(a) One-Table Design

#### **Denormalized Design**

Use this one-table design only if there is a single data source that ensures data integrity.

Copyright © 2016, by Pearson Education, Inc.,

| DeptNum | DeptName   |  |
|---------|------------|--|
| 10      | Accounting |  |
| 20      | Marketing  |  |

| EmpNum | EmpName  | DeptNum |
|--------|----------|---------|
| 100    | Jones    | 10      |
| 150    | Lau      | 20      |
| 200    | McCauley | 10      |
| 300    | Griffin  | 10      |

#### **Normalized Design**

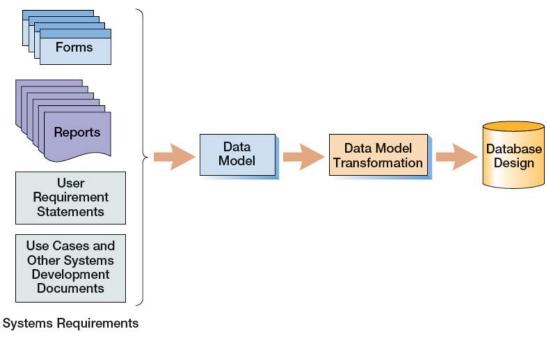

OR?

For all other cases, break the data out into multiple tables.

(b) Two-Tab e Design

#### The Need for Data Modeling

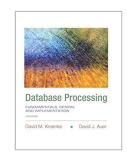

Database design has to consider

#### Homework

- Read K/A 1 and K/A 2 (up to page 61, skip 48-58).
- Complete the relevant DataCamp exercises
  - The "Intro to SQL for Data Science" course is due before Quiz 2 on November 14
- Study for Quiz 1, which covers K/A 1 plus Deals DB (part 1)

# **Databases for Analytics**

Kroenke / Auer Chapter 1
